Multiplex Synthesis (2010)

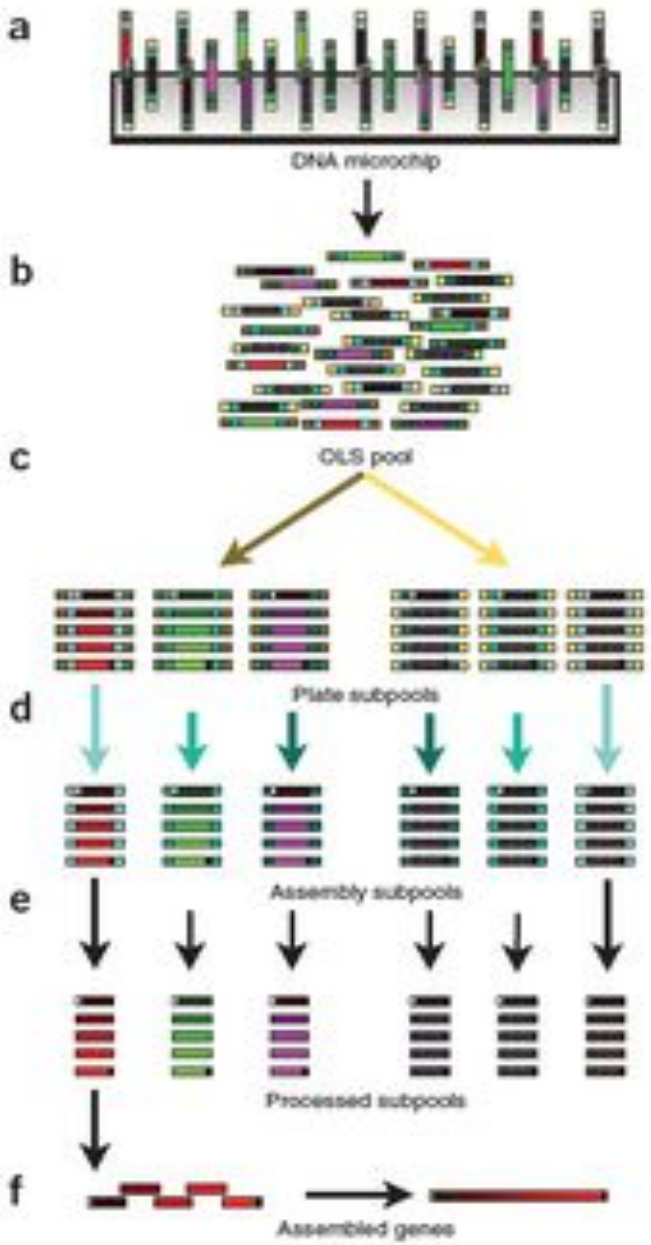

Figure 1 Schematic for scalable gene synthesis from OLS pool 2. (**a**,**b**) Pre-designed oligonucleotides (no distinction is made between dsDNA and ssDNA in the figure) are synthesized on a DNA microchip (**a**) and then cleaved to make a pool of oligonucleotides (**b**). (**c**) Plate-specific primer sequences (yellow or brown) are used to amplify separate plate subpools (only two are shown), which contain DNA to assemble different genes (only three are shown for each plate subpool). (**d**) Assembly-specific sequences (shades of blue) are used to amplify assembly subpools that contain only the DNA required to make a single gene. (**e**) The primer sequences are cleaved using either type IIS restriction enzymes (resulting in dsDNA) or by DpnII/USER/λ exonuclease processing (producing ssDNA). (**f**) Construction primers (shown as white and black sites flanking the full assembly) are then used in an assembly PCR reaction to build a gene from each assembly subpool. Depending on the downstream application, the assembled products are then cloned either before or after an enzymatic error correction step.

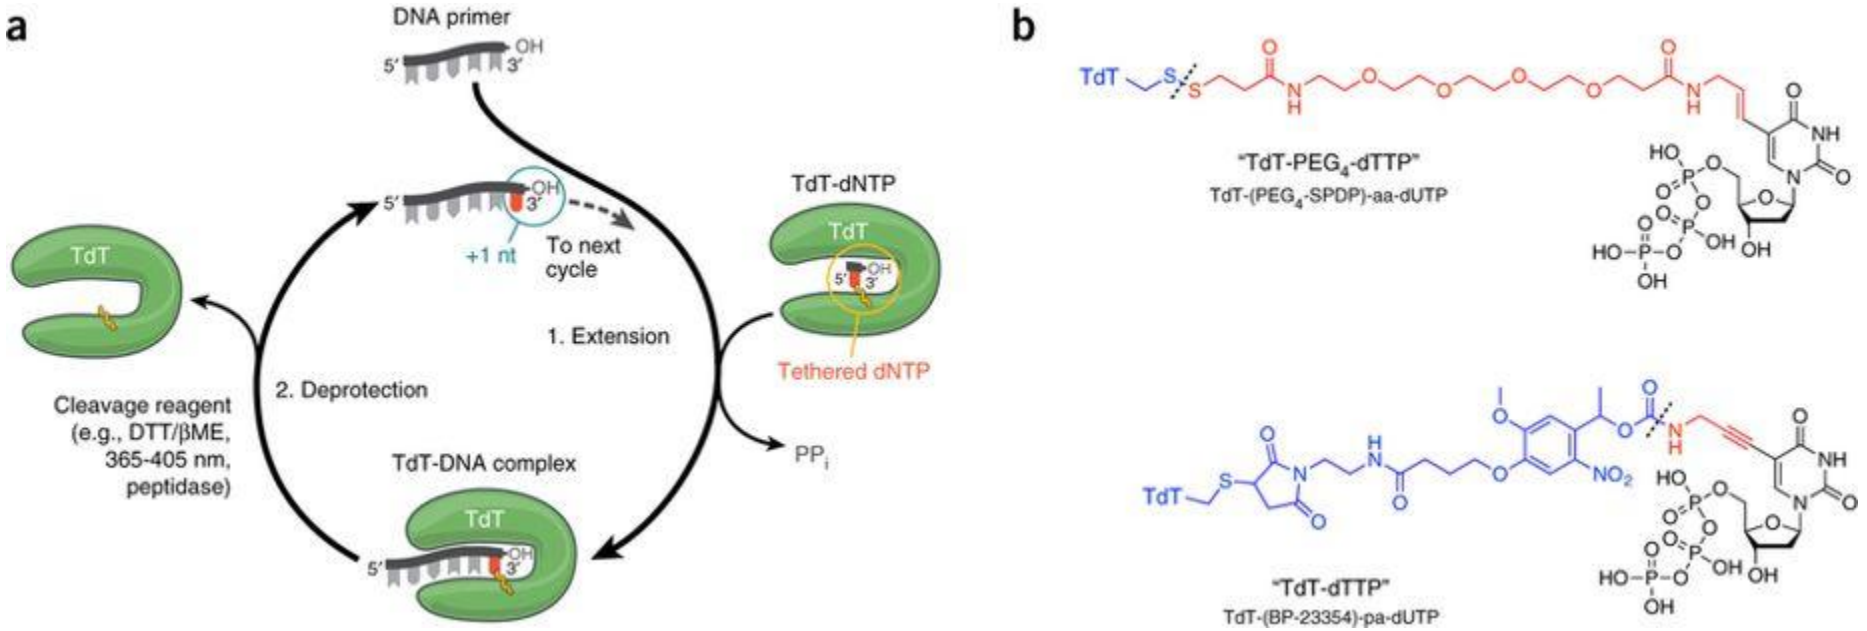
Enzymatic Synthesis

97.7% yield
20 S reaction time



(**a**) Scheme for two-step oligonucleotide extension using TdT–dNTP conjugates consisting of a TdT molecule site-specifically labeled with a dNTP via a cleavable linker. In the extension step, a DNA primer is exposed to an excess of TdT–dNTP conjugate. Upon incorporation of the tethered nucleotide into the 3′ end of the primer, the conjugate becomes covalently attached and prevents further extensions by other TdT–dNTP molecules. In the deprotection step, the remaining TdT–dNTP conjugates are inactivated (or removed) and the linkage between the incorporated nucleotide and TdT is cleaved by addition of the cleavage reagent (e.g., DTT, 365 nm light, peptidase), thereby releasing the primer for subsequent extension. The cycle can be iterated to extend a primer by a defined sequence. (**b**) Chemical structures of two types of TdT–linker-dNTP conjugates used in this study, based on the amine-to-thiol crosslinkers PEG_4-SPDP (upper, "TdT–PEG_4-dTTP") and BP-23354 (lower, "TdT–dTTP") and the dTTP analogs 5-aminoallyl dUTP (aa-dUTP) and 5-propargylamino dUTP (pa-dUTP), respectively. Upon cleavage of the linker, the atoms indicated in red remain attached to the nucleobase and are referred to as a scar. The

INTRODUCING THE SYNTAX SYSTEM:

The first DNA printer powered by Enzymatic DNA Synthesis (EDS)

REQUEST QUOTE

SYSTEM CAPABILITIES

- Fully automated DNA printer
- Plug-and-play operation

- Parallel synthesis in 96-well plates
- Up to 96 oligos per run

- 15-min setup time per run
- Same-day synthesis of 15- to 30-mers
- Longer oligos available for next-day use

OLIGO SPECIFICATIONS

- 15–60 nt *de novo* synthesis (A, T, G, and C)
- Custom iDNA 15–40 nt

- Molecular biology-ready DNA
- Default 5'-phosphate

- 200–300 pmol per well
- Normalized to 4–7 µM

Algorithmic Assembly

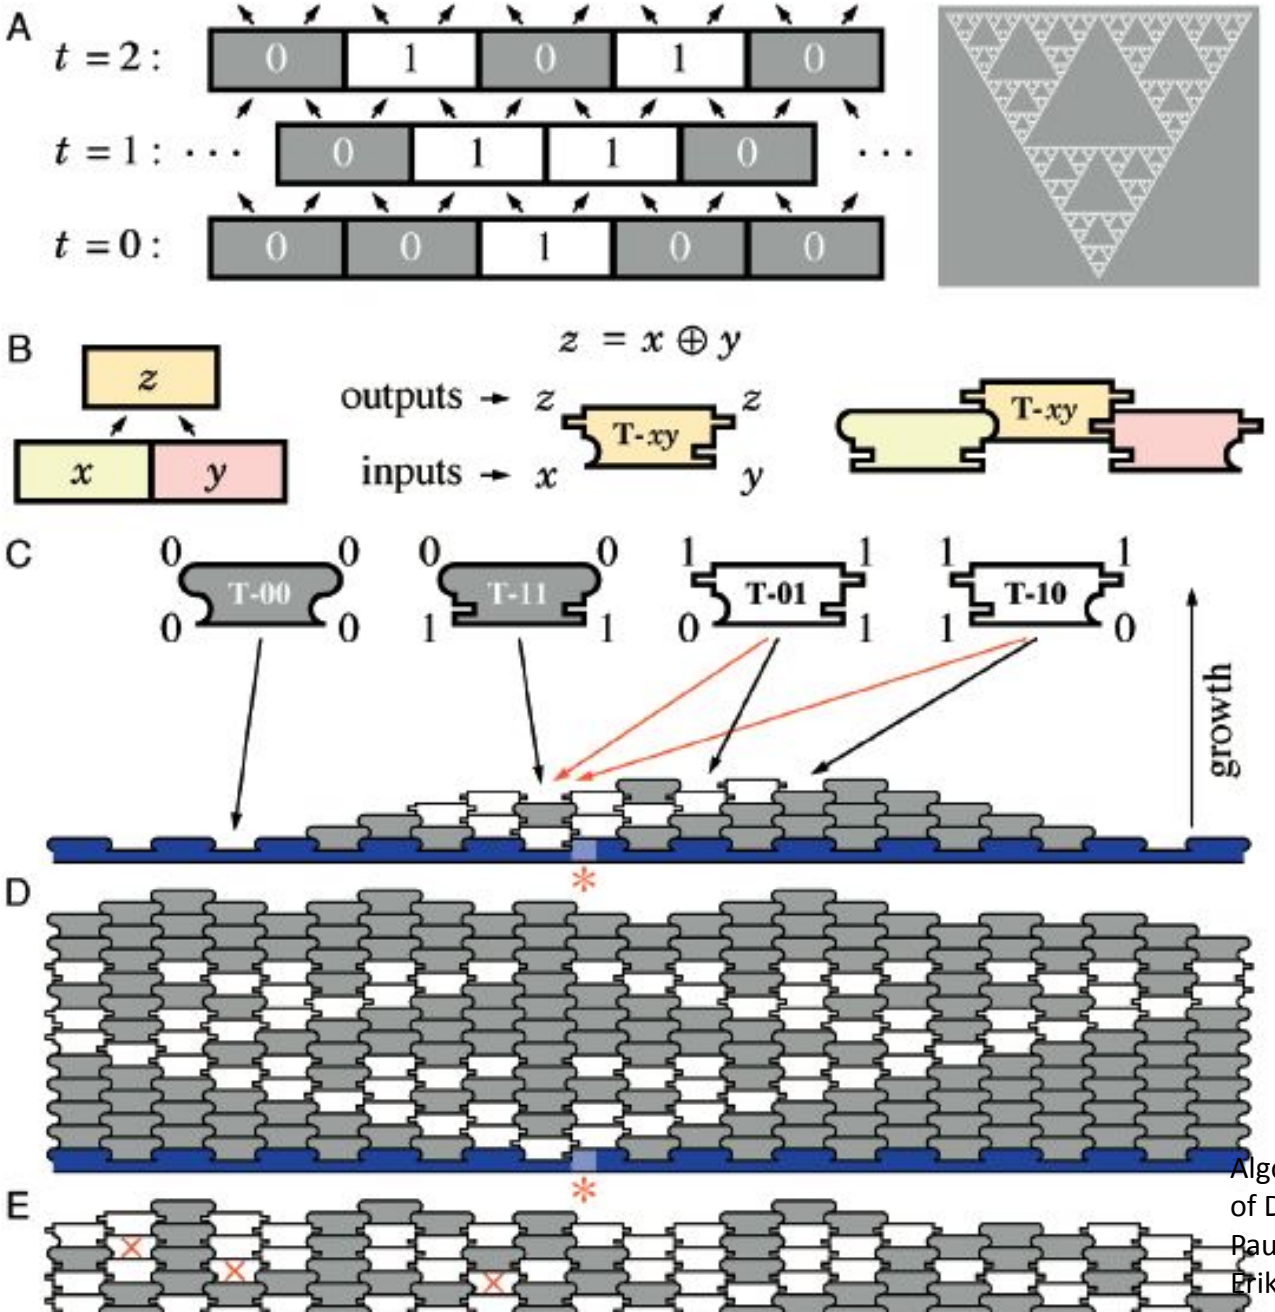

Figure 1. The XOR Cellular Automaton Its Implementation by Tile-Based S Assembly

(A) Left: three time steps of its execu drawn as a space–time history. C update synchronously according XOR by the equation shown. Cell even time steps are interleaved v those at odd time steps; arrows sl propagation of information. Right: Sierpinski triangle.

(B) Translating the space–time hist into a tiling. For each possible in pair, we generate a tile T-xy that b the inputs represented as shapes on lower half of each side and the outpu shapes duplicated on the top half of e side.

(C) The four Sierpinski rule tiles, T T-11, T-01, and T-10, represent the f entries of the truth table for X $0 \oplus 0 = 0$, $1 \oplus 1 = 0$, $0 \oplus 1 = 1$, a $1 \oplus 0 = 1$. Lower binding domains the sides of tiles match input from layer below; upper binding dom provide output to both neighbors the layer above. Semicircular dom represent '0' and rectangular doma '1'. Tiles that output '0' (T-00 and T are gray, and we refer to them as '0' t Tiles that output '1' (T-01 and T-10) white and are referred to as '1' t Initial conditions for the computat are provided by a nucleating struct (blue). Red asterisks indicate sites on nucleating structure that bear a binding domain; elsewhere, sites h all '0' binding domains. Black arr indicate associations that would f two bonds; red arrows, associations would form one bond.

(D) Error-free growth results in Sierpinski pattern.

(E) Error-prone growth from a nucl ing structure with three '1' domains. crosses indicate four mismatch error

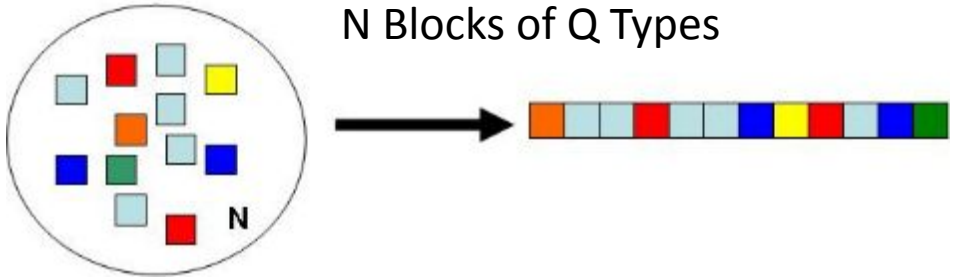
Fabricational Complexity

THE CENTER FOR BITS AND ATOMS
Massachusetts Institute of Technology

Application: Why Are There 20 Amino Acids in Biology?

(What is the right balance between Codon code redundancy and diversity?)

Question: Given N monomeric building blocks of Q different types, what is the optimal number of different types of building blocks Q which maximizes the complexity of the ensemble of all possible constructs?



The complexion for the total number of different ways to arrange N blocks of Q different types (where each type has the same number) is given by:

$$W = \frac{N!}{\prod_i n_i!} = \frac{N!}{(N/Q)!^Q}$$

And the complexity is: $F(N,Q) \approx N\ln(N) - Q^*\left[(N/Q)\ln(N/Q) - N/Q\right]$

For a given polymer length N we can ask which Q* achieves the half max for complexity such that:

$$F(N,Q^*) = 0.5F(N,N)$$
